Received 28 February 2011; accepted 3 March 2011

Key indicators: single-crystal X-ray study; $T = 100$ K; mean $\sigma(\text{C}-\text{C}) = 0.002$ Å; R factor = 0.021; wR factor = 0.053; data-to-parameter ratio = 16.4.

In the title compound, $[\text{Zn}(\text{C}_6\text{H}_{14}\text{N}_2)_2(\text{H}_2\text{O})_2]\text{Cl}_2$, the Zn(II) atom resides on a special position with site symmetry $2/m$ and is octahedrally coordinated by four N atoms from two *trans* 1,2-diaminocyclohexane ligands and two water O atoms. In the crystal, $\text{N}-\text{H}\cdots\text{Cl}$ and $\text{O}-\text{H}\cdots\text{Cl}$ hydrogen bonds link the molecules into a two-dimensional network parallel to the bc plane.

***trans*-Diaquabis(cyclohexane-1,2-diamine)zinc(II) dichloride**

K. Karimnejad, H. Khaledi and H. Mohd Ali

Comment

The title Zn^{II} complex (Fig. 1) is isostructural with a previously reported Ni^{II} complex (Capilla *et al.*, 1980). The metal center in the title complex is located on a special position with site symmetry $2/m$, and is six-coordinated in a distorted octahedral geometry. The equatorial plane is defined by four N atoms from two *trans*-1,2-diaminocyclohexane, while the axial positions are occupied by two water molecule oxygen atoms. This arrangement is similar to what was observed in an analogous Cu^{II} complex (Pariya *et al.*, 1998). In the crystal, an $\text{O}—\text{H}\cdots\text{Cl}$ interaction connects the cationic complexes and chloride anions into infinite chains along the *c*-axis. The chains are further linked by $\text{N}—\text{H}\cdots\text{Cl}$ hydrogen bonds into layers parallel to the *bc* plane.

Experimental

The colorless crystals of the title compound were obtained upon slow evaporation of an ethanolic solution (20 ml) of *trans*-1,2-diaminocyclohexane (0.23 g, 2 mmol) and zinc(II) acetate dihydrate (0.22 g, 1 mmol) in the presence of a few drops of HCl (37%).

Refinement

The C-bound hydrogen atoms were placed at calculated positions with $\text{C}—\text{H} = 0.99$ and 1.00 Å for methylene and methyne type H-atoms, respectively. The hydrogen atoms bonded to N and water molecule were located from a difference map and included with restraints: $\text{O}—\text{H} = 0.84$ (2) and $\text{N}—\text{H} = 0.88$ (2) Å. For hydrogen atoms *Uiso*(H) were set to 1.2–1.5 times *Ueq*(carrier atom).

Figures

Fig. 1. Thermal ellipsoid plot of the title compound at the 50% probability level. Hydrogen atoms are drawn as spheres of arbitrary radius. Symmetry codes: ' = $-x, -y, -z$; '' = $x, -y, -z$; ''' = $-x, y, z$.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
